

# Computer Graphics (CS 543)

## Lecture 7b: Intro to lighting, Shading and Materials + Phong Lighting Model

---

Prof Emmanuel Agu

*Computer Science Dept.  
Worcester Polytechnic Institute (WPI)*

# Why do we need Lighting & shading?

- Has **visual cues** for humans (shape, light position, viewer position, surface orientation, material properties, etc)

**Sphere without  
lighting & shading**

**Sphere with  
lighting & shading**

# What Causes Shading?

- Shading caused by different angles with light, camera at different points

# Lighting?

- **Lighting problem:** Calculate surface color based on angle of surface with light, viewer
- Programmer writes vertex shader code to calculate lighting **at vertices!**
- Equation for lighting calculation = **lighting model**

# Shading?

- After triangle is rasterized (converted to pixels)
  - Per-vertex lighting calculation means color at vertices is accurate, known (**red dots**)
- Shading: Graphics hardware figures out color of interior pixels (**blue dots**)
- How? Assume linear change => interpolate

Lighting  
(calc at vertices  
in vertex shader)

Rasterization  
Find pixels belonging  
to each object

Shading  
(done in hardware  
during rasterization)

# Global Illumination (Lighting) Model

- **Global illumination:** model interaction of light from all surfaces in scene (track multiple bounces)

# Rendering Equation

- The infinite reflection, scattering and absorption of light is described by the *rendering equation*
  - Includes many effects (Reflection, Shadows, etc)
- Mathematical basis for all global illumination algorithms

$$L_o = L_e(x, \vec{\omega}) + \int_{\Omega} fr(x, \vec{\omega}', \vec{\omega}) Li(x, \vec{\omega}') (\vec{\omega}' \cdot \vec{n}) d\vec{\omega}'$$

- $L_o$  is outgoing radiance
- $L_i$  incident radiance
- $L_e$  emitted radiance,
- $fr$  is bidirectional reflectance distribution function (BRDF)
  - Fraction of incident light reflected by a surface

# Local Illumination (Lighting) Model

- One bounce!
  - Doesn't track inter-reflections, transmissions (e.g. OpenGL)

- Global Illumination (GI) is accurate, looks real
  - But raster graphics pipeline (e.g. OpenGL) renders each polygon independently (local rendering), no GI

# Light Sources

- General light sources are difficult to model (e.g. light bulb)
- Why? We must compute effect of light coming from all points on light source

# Light Sources Abstractions

- We generally use simpler light sources
- Abstractions that are easier to model

Point light

Directional light

Spot light

Area light

Light intensity can be **independent** or **dependent** of the distance between object and the light source

# Light-Material Interaction

- White light strikes object, some wavelengths (colors) absorbed, some reflected
- Fraction reflected determines object color and brightness
  - **Example:** A surface looks red under white light because red component of light is reflected, other wavelengths absorbed

# Phong Model

- Simple lighting model that can be computed quickly
- 3 components
  - Diffuse
  - Specular
  - Ambient
- Compute each component separately
- Vertex Illumination =  
**ambient + diffuse + specular**
- Materials reflect each component differently

# Phong Model

- Compute lighting (components) at each vertex ( $P$ )
- Uses 4 vectors, from vertex
  - To light source ( $\mathbf{l}$ )
  - To viewer ( $\mathbf{v}$ )
  - Normal ( $\mathbf{n}$ )
  - Mirror direction ( $\mathbf{r}$ )

# Mirror Direction?

- Angle of reflection = angle of incidence
- Normal is determined by surface orientation

$$\mathbf{r} = 2 (\mathbf{l} \cdot \mathbf{n}) \mathbf{n} - \mathbf{l}$$

# Surface Roughness

- **Smooth surfaces:** more reflected light concentrated in mirror direction
- **Rough surfaces:** reflects light in all directions

smooth surface

rough surface

# Diffuse Lighting Example

# Diffuse Light Calculation

- How much light received from light source?
- Based on Lambert's Law

Receive more light

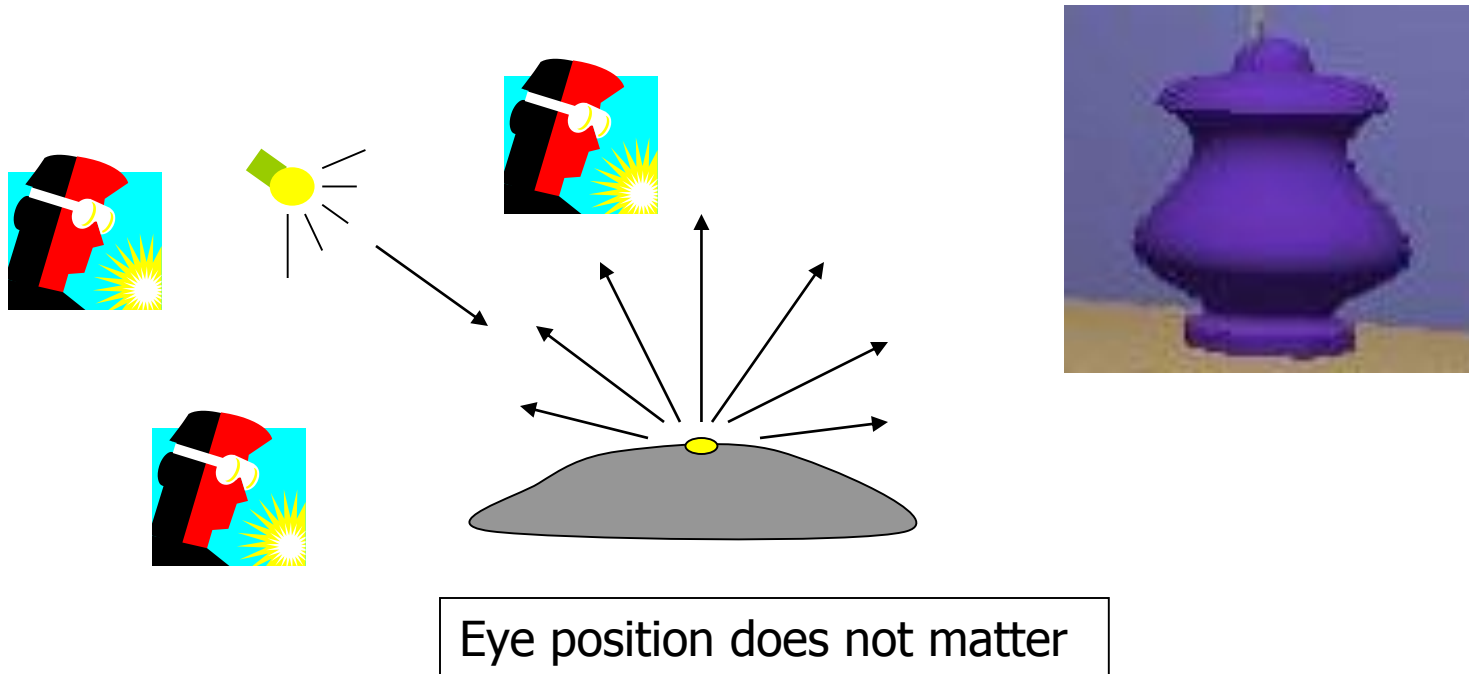

Receive less light

# Diffuse Light Reflected

- Illumination surface received from light source, reflected equally in all directions

# Diffuse Light Calculation

- Lambert's law: radiant energy  $D$  a small surface patch receives from a light source is:

$$D = I \times k_D \cos(\theta)$$

- $I$ : light intensity
- $\theta$ : angle between light vector and surface normal
- $k_D$ : Diffuse reflection coefficient.  
Controls how much diffuse light surface reflects

# Specular light example

**Specular?  
Bright spot  
on object**

# Specular light contribution

- Incoming light reflected out in small surface area
- Specular depends on viewer position relative to mirror direction
- Specular bright in **mirror direction**
- Drops off away from mirror direction

# Specular light calculation

- $\phi$  is deviation of view angle from mirror direction
- Small  $\phi$  = more specular

# The Shininess Coefficient, $\alpha$

- $\alpha$  controls falloff sharpness
- High  $\alpha$  = sharper falloff = small, bright highlight
- Low  $\alpha$  = slow falloff = large, dull highlight
  - $\alpha$  between 100 and 200 = metals
  - $\alpha$  between 5 and 10 = plastic look

# Specular light: Effect of ' $\alpha$ '

$$\mathbf{I}_s = k_s \mathbf{I} \cos^{\alpha} \phi$$

$\alpha = 10$

$\alpha = 90$

$\alpha = 30$

$\alpha = 270$

# Ambient Light Contribution

- Very simple approximation of global illumination (Lump 2<sup>nd</sup>, 3<sup>rd</sup>, 4<sup>th</sup>, .... etc bounce into single term)
- **Assume to be a constant**
- No direction!
  - Independent of light position, object orientation, observer's position or orientation

$$\text{Ambient} = I_a \times K_a \leftarrow \text{constant}$$

# Ambient Light Example

**Ambient:** background light, scattered by environment

# Light Attenuation with Distance

- Light reaching a surface **inversely proportional** to square of distance **d**
- We can multiply by factor of form  $1/(ad + bd + cd^2)$  to **diffuse** and **specular** terms

# Adding up the Components

- Adding all components (no attenuation term), phong model for each light source can be written as

**diffuse** + **specular** + **ambient**

$$I = k_d I_d \cos\theta + k_s I_s \cos\phi^\alpha + k_a I_a$$
$$= k_d I_d (\mathbf{l} \cdot \mathbf{n}) + k_s I_s (\mathbf{v} \cdot \mathbf{r})^\alpha + k_a I_a$$

- **Note:**

- $\cos\theta = \mathbf{l} \cdot \mathbf{n}$
- $\cos\phi = \mathbf{v} \cdot \mathbf{r}$

# Separate RGB Components

- Can separate red, green and blue components. Instead of:

$$I = k_d I_d (\mathbf{l} \cdot \mathbf{n}) + k_s I_s (\mathbf{v} \cdot \mathbf{r})^\alpha + k_a I_a$$

- We computing lighting for RGB colors separately

$$I_r = k_{dr} I_{dr} \mathbf{l} \cdot \mathbf{n} + k_{sr} I_{sr} (\mathbf{v} \cdot \mathbf{r})^\alpha + k_{ar} I_{ar} \quad \text{Red}$$

$$I_g = k_{dg} I_{dg} \mathbf{l} \cdot \mathbf{n} + k_{sg} I_{sg} (\mathbf{v} \cdot \mathbf{r})^\alpha + k_{ag} I_{ag} \quad \text{Green}$$

$$I_b = k_{db} I_{db} \mathbf{l} \cdot \mathbf{n} + k_{sb} I_{sb} (\mathbf{v} \cdot \mathbf{r})^\alpha + k_{ab} I_{ab} \quad \text{Blue}$$

- Above equation is just for one light source!!
- For N lights, repeat calculation for each light

**Total illumination for a point P =  $\Sigma$  (Lighting for all lights)**

# Coefficients for Real Materials

<b>Material</b>	<b>Ambient Kar, Kag,kab</b>	<b>Diffuse Kdr, Kdg,kdb</b>	<b>Specular Ksr, Ksg,ksb</b>	<b>Exponent, <math>\alpha</math></b>
<b>Black plastic</b>	<b>0.0 0.0 0.0</b>	<b>0.01 0.01 0.01</b>	<b>0.5 0.5 0.5</b>	<b>32</b>

Figure 8.17, Hill, courtesy of McReynolds and Blythe

# Modified Phong Model

$$I = k_d I_d \mathbf{l} \cdot \mathbf{n} + k_s I_s (\mathbf{v} \cdot \mathbf{r})^\alpha + k_a I_a$$

$$I = k_d I_d \mathbf{l} \cdot \mathbf{n} + k_s I_s (\mathbf{n} \cdot \mathbf{h})^\beta + k_a I_a$$

Used in  
OpenGL

- Blinn proposed using **halfway vector**, more efficient
- **h** is normalized vector halfway between **l** and **v**
- Similar results as original Phong

$$\mathbf{h} = (\mathbf{l} + \mathbf{v}) / |\mathbf{l} + \mathbf{v}|$$
