Computer Graphics (CS 543) Lecture 9b: Shadows and Shadow Maps

Prof Emmanuel Agu

Computer Science Dept. Worcester Polytechnic Institute (WPI)

Introduction to Shadows

Shadows give information on relative positions of objects¹

Why shadows?More realism and atmosphere

Types of Shadow Algorithms

- Project shadows as separate objects (like Peter Pan's shadow)
 - Projective shadows
- As volumes of space that are dark
 - Shadow volumes [Franklin Crow 77]
- As places not seen from a light source looking at the scene
 - Shadow maps [Lance Williams 78]
- Fourth method used in ray tracing

Projective Shadows

- Oldest method: Used in early flight simulators
- Projection of polygon is polygon called shadow polygon

Projective Shadows

- Works for flat surfaces illuminated by point light
- For each face, project vertices V to find V' of shadow polygon
- Object shadow = union of projections of faces

Projective Shadow Algorithm

- Project light-object edges onto plane
- Algorithm:
 - First, draw ground plane/scene using specular+diffuse+ambient components
 - Then, draw shadow projections (face by face) using only ambient component

Projective Shadows for Polygon

- 1. If light is at (x_1, y_1, z_1)
- 2. Vertex at (x, y, z)
- Would like to calculate shadow polygon vertex V projected onto ground at (x_p, 0, z_p)

Projective Shadows for Polygon

- If we move original polygon so that light source is at origin
- Matrix *M* projects a vertex V to give its projection V' in shadow polygon

$$m = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{-y_{l}} & 0 & 0 \\ & -y_{l} & & \end{bmatrix}$$

Building Shadow Projection Matrix

- 1. Translate source to origin with $T(-x_1, -y_1, -z_1)$
- 2. Perspective projection
- 3. Translate back by $T(x_i, y_i, z_i)$

$$M = \begin{bmatrix} 1 & 0 & 0 & x_l \\ 0 & 1 & 0 & y_l \\ 0 & 0 & 1 & z_l \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -y_l & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & -x_l \\ 0 & 1 & 0 & -y_l \\ 0 & 0 & 1 & -z_l \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Final matrix that projects Vertex V onto V' in shadow polygon

Code snippets?

Set up projection matrix in OpenGL application

float light[3]; // location of light
mat4 m; // shadow projection matrix initially identity

```
M[3][1] = -1.0/light[1];
M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{-y_{1}} & 0 & 0 \\ -y_{1} & 0 & 0 \end{bmatrix}
```

Projective Shadow Code

• Set up object (e.g a square) to be drawn

```
point4 square[4] = {vec4(-0.5, 0.5, -0.5, 1.0}
{vec4(-0.5, 0.5, -0.5, 1.0}
{vec4(-0.5, 0.5, -0.5, 1.0}
{vec4(-0.5, 0.5, -0.5, 1.0}
```

- Copy square to VBO
- Pass modelview, projection matrices to vertex shader

What next?

- Next, we load model_view as usual then draw original polygon
- Then load shadow projection matrix, change color to black, re-render polygon

Shadow projection Display() Function

```
void display()
{
    mat4 mm;
    // clear the window
    glClear(GL_COLOR_BUFFER_BIT | GL_DEPTH_BUFFER_BIT);
    // render red square (original square) using modelview
    // matrix as usual (previously set up)
    glUniform4fv(color_loc, 1, red);
    glDrawArrays(GL_TRIANGLE_STRIP, 0, 4);
```

Shadow projection Display() Function

```
11
    modify modelview matrix to project square
// and send modified model view matrix to shader
mm = model view
        * Translate(light[0], light[1], light[2]
        *m
        * Translate(-light[0], -light[1], -light[2]);
glUniformMatrix4fv(matrix loc, 1, GL TRUE, mm);
//and re-render square as
// black square (or using only ambient component)
 glUniform4fv(color loc, 1, black);
 glDrawArrays (GL TRIANGLE STRIP, 0, 4);
 glutSwapBuffers();
                                                        M = \begin{bmatrix} 1 & 0 & 0 & x_l \\ 0 & 1 & 0 & y_l \\ 0 & 0 & 1 & z_l \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{-\mathcal{V}_l} & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & -x_l \\ 0 & 1 & 0 & -y_l \\ 0 & 0 & 1 & -z_l \\ 0 & 0 & 0 & 1 \end{bmatrix}
```

Shadow Buffer Theory

- Along each path from light
 - Only closest object is lit
 - Other objects on that path in shadow
- Shadow buffer stores closest object on each path

Shadow Map Illustrated

ed

Not limited to planes

- Second dept buffer called the shadow map is used
- Point v_a stored in element a of shadow map: lit!
- Point v_h NOT in element b of shadow map: In shadow

Shadow Map: Depth Comparison

Render depth image from light

Camera's view

OpenGL Depth Buffer (Z Buffer)

- **Depth:** While drawing objects, depth buffer stores distance of each polygon from viewer
- Why? If multiple polygons overlap a pixel, only closest one polygon is drawn

Setting up OpenGL Depth Buffer

- Note: You did this in order to draw solid cube, meshes
- glutInitDisplayMode (GLUT_DEPTH | GLUT_RGB) instructs openGL to create depth buffer
- 2. **glEnable (GL_DEPTH_TEST)** enables depth testing
- 3. glClear(GL_COLOR_BUFFER_BIT GL_DEPTH_BUFFER_BIT

Initializes depth buffer every time we draw a new picture

Shadow Map Approach

- Rendering in two stages:
 - Loading shadow Map
 - Render the scene

Loading Shadow Map

- Initialize each element to 1.0
- Position a camera at light source
- Rasterize each face in scene updating closest object
- Shadow map (buffer) tracks smallest depth on each path

Shadow Map (Rendering Scene)

- Render scene using camera as usual
- While rendering a pixel find:
 - pseudo-depth D from light source to P
 - Index location [i][j] in shadow buffer, to be tested
 - Value d[i][j] stored in shadow buffer
- If d[i][j] < D (other object on this path closer to light)
 - point P is in shadow
 - lighting = ambient
- Otherwise, not in shadow
 - Lighting = amb + diffuse + specular

Loading Shadow Map

- Shadow map calculation is independent of eye position
- In animations, shadow map loaded once
- If eye moves, no need for recalculation
- If objects move, recalculation required
